Getting cloud right
How can organisations stay ahead of the curve?
Executive Summary

“More than half of all European enterprise infrastructure technology decision makers say their firms have adopted public cloud (56%) and 70% actively consider migration to be part of their plans.” [1]

Cloud’s benefits and value for organisations
Cloud enables organisations to improve their competitiveness and agility, get relieved from physical infrastructure management, drive innovation by tapping cutting-edge technology, leverage industry-specific solutions and shift their spending paradigm from CapEx to OpEx.

Why have organisations been reluctant to use cloud?
Regulations, data security, cloud transformation challenges and the risks associated with the outsourcing of critical processes have so far discouraged organisations from using cloud services. To help clients cope with regulations, major cloud service providers have increased their global physical presence, which in some cases resolved issues regarding the obligation to host data within the country where data is collected. Transformation challenges can be overcome by adopting a structured approach to cloud adoption, while a thorough risk assessment and ongoing vendor management process enable organisations to mitigate data and third party risks.

Cloud cyber security
Cloud services extend the IT footprint of organisations, increasing the cyber attack surface, which calls for robust arrangements around cyber security. Fortunately, major cloud service providers offer built-in, state-of-the-art solutions to secure cloud systems in a holistic manner across all Cyber Risk domains, supporting Network and Infrastructure Security, Identity and Access Management (IAM), Data Protection, Logging and Monitoring, Resilience, DevSecOps, and Governance, Risk & Compliance. Depending on the service delivery model, a significant part of Cybersecurity responsibilities may be covered by the cloud service provider, most notably when using Software-as-a-Service (SaaS).

Compliance with regulatory requirements
Using cloud services raises questions about compliance with regulations, since processing sensitive information or client identifying data (CID) comes under strict rules. Using cloud services hosted within the same jurisdiction where data is collected addresses the challenge in some scenarios – however, since regulations differ between countries, this report only presents general considerations, while country-specific considerations may be obtained from your local Deloitte offices.
Introduction

Cloud is not the future or an emerging trend anymore: it is the present and it constitutes a critical tool for organisations to stay competitive in today’s challenging business environment. Success with process re-engineering and efforts at digitalisation with emerging technologies such as artificial intelligence are dependent on cloud computing.

Some regulators and supervisors recently published guidelines to encourage a more extensive use of cloud services, whilst at the same time stating that organisations cannot relinquish their accountability of outsourced IT services.

This report provides an independent perspective on the major opportunities and risk management issues, but also - based on our practical experience - a high-level roadmap to cloud transformation and the common pitfalls that organisations should consider. This report also provides tools to answer certain questions about IT:

- How can we seize opportunities while mitigating risks?
- How can we keep up with innovation while not making costly mistakes?
- How do we survive and thrive in the cloud?

Leveraging cloud offerings represents a shift in management attitudes – organisations are moving away from a do-it-yourself mentality towards using external providers with scalable, flexible, faster and sometimes cheaper services. While some organisations are apprehensive about using the cloud, it is an integral component of today’s service-delivery model and it enables tapping into new market opportunities and access new delivery channels.

Many suppliers and organisations are therefore moving to a ‘cloud first’ strategy. Cloud deployments with off-the-shelf offerings are becoming ubiquitous, while on-premise deployments are becoming the exception. Many RegTech companies offer software as a service out of the cloud. Industry-focussed boutiques offer managed services which are already compliant with the industry’s regulations across all technology layers (from the infrastructure up to the software), enabling highly regulated companies such as banks to accelerate their adoption of the cloud by providing out-of-the-box compliance with industry-specific regulations.
“Many large corporations have tended to prefer private cloud or a public/private hybrid because of the additional security, perceived or actual, it provides. This hesitancy on the part of large companies is disappearing. Where they can, they now tend to deploy public rather than private cloud.” [3]
Cloud quick check – Is your organisation getting cloud right?

Do we understand how cloud can help us reach our strategic objectives?
- Yes
- Better get some advice

Do we know which parts of our business will benefit from cloud?
- Yes
- Better get some advice

Is your team nervous about transitioning to the cloud?
- Yes
- Better get some advice

Do you know what your competitors are doing with cloud?
- Yes
- Better get some advice

Can our organisation remain competitive without using cloud?
- Yes
- Better get some advice

Cloud specifications and meaning

What is the cloud? The cloud consists of a broad range of offerings where services are provided by an external third party and purchased as a service. Offerings vary from basic computing resources, to platforms, to fully functional software ready to deliver business value. These are referred to respectively as Infrastructure as a Service (IaaS), Platform as a Service (PaaS) and Software as a Service (SaaS).

Cloud deployment models

- **Public cloud** (off-premise or external): cloud computing services provided by suppliers to multiple customers via a cloud computing architecture that allows customers to share computing resources. Swisscom Cloud or DigitalOcean are examples of public clouds. A **hyperscale public cloud** is a category of public cloud providing a larger pool of resources, serving millions of users and combining hundred thousands of individual computers into a low cost resource pool with maximum availability. Amazon Web Services, Microsoft Azure and Google Cloud are prominent providers of hyperscale public clouds.

- **Private cloud** (on-premise or internal): cloud computing services owned and operated on-site by a single organisation.

- **Hybrid cloud** (integrated public and private service): a mixed environment combining public cloud and private cloud.

- **Community cloud**: a public or private cloud shared by an industry group, government agency, or other association with similar demands or interests.
Cloud delivery models

- **Infrastructure as a Service (IaaS)**
This provides low-level resources such as computing, storage and networking for customers to build scalable applications. AWS EC2 is an example of IaaS providing ‘virtual machines’.

- **Platform as a Service (PaaS)**
One level above IaaS, PaaS provides a managed environment to develop applications such as a Java runtime or a NoSQL database. Google Cloud’s App Engine is an example of PaaS providing a managed Java, Python, Go or node.js environment for developing applications without the need to manage the underlying infrastructure.

- **Software as a Service (SaaS)**
This provides user-ready, out-of-the-box software providing a specific built-for-purpose business service to the customer. Microsoft’s Office 365 is an example of a SaaS, where customer can use the service without managing any aspects of the underlying software and infrastructure.

- **Managed Services (MS)**
MS are an additional layer of services delivered on top of cloud services, to manage processes such as 24/7 SLA monitoring, operational management, liability frameworks, ecosystem integration, audit, security, fail-over management, compliance and other processes.

- **Business Process as a Service (BPaaS)**
BPaaS is a form of Business Process Outsourcing (BPO) that employs a cloud computing service model to deliver automated services sourced from the cloud and operated within a shared multi-tenant infrastructure. Whereas the aim of traditional BPO is to reduce labour costs, BPaaS reduces labour costs through increased automation and economies of scale. As an example, Deloitte’s BPaaS offerings provide managed logs analytics and managed cyber risk with specific industry skills, especially for customers in highly-regulated industries.

- **Cloud stack**
A cloud stack is a software layer that can be deployed on computing infrastructure to provide a cloud environment. As an example, Microsoft installs an Azure layer or stack on top of dedicated hardware (e.g. HPE, Dell or Lenovo) which creates the Azure environment. An Azure stack can also be deployed in a private data centre to simulate some features of Azure cloud in a private environment.
“Organisations often struggle to define a cloud strategy, or to link it to their broader business strategy. Consequently, they find it difficult to generate genuine business value from this type of digital transformation. Cloud has most definitely arrived and is here to stay as a key element of corporate strategy – not just IT strategy, but overall business strategy.” [3]
Benefits of the cloud for organisations

Running a business in the cloud offers numerous advantages, depending on the industry, business size and location. Deloitte has grouped the potential benefits into the following four categories:

- Improve business agility
- Innovate through consumption of external services
- Leverage industry-specific solutions
- Paradigm shift in IT spending

Each of these attributes brings valuable benefits when implementing a cloud strategy. For example, a shift in spending can enable companies to reduce working capital and free up cash to invest in the exploration of new technologies; while an improvement in agility can facilitate innovation and also accelerate the shift towards IT service consumption instead of IT ownership, which impacts the spending paradigm. A successful cloud transformation should capture benefits across all four areas.
Improve business agility

Major organisations heavily rely on legacy systems which restrict business agility. The rise of the digital economy has put pressure on industry players, and triggered the need to pursue digital transformation and integrate new digital technologies quickly in order to respond to changes in the market and consumer behaviour. Legacy systems sometimes do not provide the appropriate level of agility that is needed to keep up with the pace of change. Contemporary startups and companies were created ‘digital and cloud native’. Disruptors are not only able to deliver solutions at much faster pace; they also attract customers and gain market share due to their user-friendly and innovative solutions, fuelled by an agile, cloud based infrastructure. Deloitte recommends a multi-stage approach for traditional organisations to move away from legacy systems towards the cloud. This begins with an evaluation of the suitability of the cloud for key applications and processes, and a gradual shift from legacy systems towards the public cloud (if compatible with regulations) since this type of cloud model yields the most benefits in terms of elasticity, functionality and cost efficiency. A hybrid cloud architecture is the golden standard today, but there will be an increasing shift towards the public cloud due to the benefits from hyperscale cloud services.

“Many organisations around the world are aggressively pursuing a mobile-first strategy. Some have launched mobile-only brands to fend off digital challengers, while a vast majority are enhancing their mobile apps with new features and more user-friendly interfaces.” [4]
Stages in the journey from legacy systems to the cloud

**Key activities**
- Establish IT baseline
- Discuss vision
- Develop high-level strategy
- Identify preferred cloud vendors
- Introduce private and public cloud
- Define governance around the new environments
- Complete financial and suitability analysis
- Rationalise applications

**Frequently asked questions**
- What can I do to run my IT for less money?
- What is cloud and how can I make use of it?
- How do I make sure I get the best value out of cloud?
- What is my concrete cloud strategy in practice?
Hybrid Cloud

**Key activities**

- Adapt target operating model
- Evaluate business case for each legacy application and define target environment
- Migrate, replace, re-platform or retain legacy applications
- Begin integration of different environments

**Frequently asked questions**

- When can I see the tangible financial/process advantages?
- How does this affect my organisation as a whole?

- How can I adapt my organisation to increase my benefits from cloud?
Innovate through consumption of external services

Organisations need to embrace the cloud to fully re-imagine processes. For many organisations, one of the way to be competitive in the future will be to embrace big data across all its product offerings and leverage AI to change the customer experience. It is difficult to re-imagine a modern, data-driven digital strategy without an underlying cloud platform to provide at-scale computing and storage.

Cloud success stories

HP Inc. handles more than 600 million technical support contacts each year. To improve both self-service and contact center support delivery, HP built a virtual agent using the Microsoft Dynamics 365 AI solution for customer service. Customers can now interact conversationally with the assistant to solve common problems, support staff use the Microsoft AI solution for instant access to a wealth of troubleshooting information, and the company gains deeper insights into common customer issues. [5]

Citigroup and IBM [6]: “Citigroup was seeking to reduce time to market for the company’s more than 20,000 internal applications. Developers who were usually forced to wait up to 45 days for infrastructure resources to be provisioned could access servers in less than 20 minutes using IBM Cloud, streamlining development cycles and drastically reducing the time to value for the company to deliver applications to their customers.”

Disruptive technologies are strategic assets in today’s competitive marketplace, but adopting and extracting value from them within a reasonable timeframe can be a challenge. What if you could tap new technologies as an outsourced service, instead of hosting and owning them? By giving access to a range of specialised tools and services, cloud services provide an ecosystem of Centres of Excellence that can be accessed rapidly through the Internet, making organisations more competitive. State-of-the-art cloud platforms offer key capabilities in strategic domains such as analytics (Google Cloud’s Dataproc), blockchain (AWS Blockchain) and distributed mobile applications (Azure Mobile Apps) enabling software development teams to stay ahead of the innovation curve. Developing or owning new technologies becomes an obsolete burden when they can be used as a service in a seamless manner.

Leverage industry-specific solutions

Using IaaS or PaaS to build applications offers enormous flexibility in terms of design and functionality; however, flexibility also comes with challenges. Highly-regulated industries such as insurance, banking or life sciences have a complex burden of regulations and compliance, which makes a do-it-yourself option for applications development both costly and risky. Industry-focussed solutions delivered as higher level services such as SaaS or BPaaS can provide an out-of-the-box solution and help organisations cope with the regulatory burden by ensuring regulatory compliance, auditability, transparency and security along the whole value chain, from the provision of infrastructure to the delivery of the service to the end-user. A Managed Services provider can guarantee end-to-end responsibility and act as a single point of contact, greatly simplifying operations and management.
Paradigm shift in IT spending

Cloud provides a shift from CapEx (Capital Expenditure) to OpEx (Operational Expenditure), switching from asset ownership to service consumption. The following advantages emerge from this change in ownership structure:

• **Flexible pricing** (only pay for what you use). Only consumed services are charged for. This may lead to cost savings, especially for punctual and intensive workloads such as daily, monthly and year-end processing. However, there may or may not be cost savings, depending on the company’s use of the cloud.

• **No upfront infrastructure investment.** Avoiding large upfront costs enables organisations to improve their working capital, enabling them to pursue other ventures for growth or innovation. It is important to keep in mind that some upfront costs such as costs of integration, connectivity and migration can still be incurred when moving to the cloud.

• **No depreciation, renewal costs or obsolescence of infrastructure.** With the purchase of infrastructure there is always the risk of aging and obsolescence: this can be avoided by consuming resources as a cloud service.

**Cloud success stories**

“McKesson migrated their SAP solution to Google Cloud to gain insights with advanced healthcare analytics.” [7]

Financial services provider Allianz, one of the world’s largest insurance companies, deployed its Oracle Exadata-powered business intelligence stack in Oracle Cloud. [8]
Why have organisations been reluctant to use the cloud?

Organisations have been reluctant to use the cloud mainly because of four roadblocks:

- Regulations
- Data security
- Third-party risk
- Transformation challenges
Regulations

National regulatory authorities often insist that data held by domestic companies should be kept only on servers in that country, and that access to data should only be possible from within the country. Furthermore, they may impose legal obligations relating to investigations or data recovery, or about the location of employees. This means that a cloud service provider has to use local servers, which creates a major challenge for the operating model of global cloud service providers.

Major cloud service providers have tried to increase their global footprint by building more data centres in new locations close to their customers. This helps organisations meet some of the regulatory requirements by having data physically located in the same country.

Data security

Keeping data safe from unauthorised external access or damage/corruption is a challenge for every industry. Client-side encryption guarantees that an external party or even the cloud service provider cannot access data, since the organisation - not the cloud service provider - holds the encryption and decryption keys, making it impossible for the cloud service provider to access readable data. However, client side encryption may affect performance and significantly limit the benefits of the cloud, such as search capabilities, artificial intelligence and analytics – thus a trade-off between functionality and security must be found. Integration with on-premise solutions for data management, identity and access management policies and other security systems should also be considered. In the case of SaaS or BPaaS, data cannot be accessed by the cloud service provider unless it is agreed or needed to provide the service, for example to restore data or ensure business continuity. In order for organisations to pursue the optimal strategy and processes to protect information, Data Protection & Privacy should be a pillar in their cyber security strategy.
The case of Switzerland: How do Swiss regulated organisations cope with regulations around cloud?

Microsoft Azure and Google Cloud offer organisations cloud services from data centre locations in the regions of Geneva and Zurich, providing data residency in Switzerland to support Swiss companies and institutions – including within regulated industries such as financial services and life sciences - in the next steps of their digital transformation. [10] [11]

IBM, Swisscom and other providers offer private cloud services, in addition to the before mentioned hyperscale cloud services from Google and Microsoft.
Deloitte’s holistic cloud security framework

**Vigilance**
- Monitor security information and events for malicious activity/usage within cloud services
- Identify, prioritise and remediate vulnerabilities for cloud services
- Dashboards to enable security operations teams
- Intelligence to identify threats to your cloud services and providers

**Risk management**
- Visibility into cloud usage to discover Shadow IT
- Ranking and scoring the security capabilities of the cloud providers
- Dashboards to enable decisions about risk and compliance in the cloud
- Define and enforce cloud policies and standards

**Data protection & privacy**
- Visibility into data usage in the cloud
- Centralised data protection policy management
- Application of data protection and privacy controls like encryption, tokenisation, data loss prevention, and digital rights management for use with cloud services
Third-party risks

Running central systems in the cloud creates a dependency on the cloud service provider. This calls for a risk assessment and vendor management process to ensure alignment between the business objectives and service delivery from the cloud service provider. From a technological point of view, relying on a cloud service provider to run critical systems in the cloud should not be considered riskier than running the same systems on-premise, provided that the cloud service provider is compliant with regulations (e.g. for data retention, data access, auditability) and the appropriate design and best practices are implemented. To mitigate supplier risks, organisations should implement a process to manage the lifecycle of the supplier relationship and clearly align business goals with the services from the cloud service provider, while also managing risks and maintaining an exit plan.

The IT vendor management operating model consists of four phases and is a continuous activity that takes place after the procurement of services.

**Mobilisation** is the initial setup of the Vendor Management activities. This phase includes a final check of key clauses before contract signature and the mobilisation of the team and processes to support the new arrangement.

**Manage** phase spans the entire contract term and involves carrying out processes and activities required to robustly manage the vendor.

**Develop** phase focuses on deriving the maximum value from the vendor relationship.

**Exit Preparation** prepares for the termination or renewal stages of the agreement with the vendor.

*Vendor Managers should be involved in the final stages before contract signature to check service scope is clear, SLAs are in place, pricing / invoicing is clear.*

**Figure 5 - source: Deloitte**
Transformation challenges

Major organisations across all industries rely heavily on systems that run legacy applications. In order to move these applications to the cloud and fully reap the benefits of such a transformation, applications need to go through re-design and refactoring, which can be a costly and risky step. Simply switching virtual machines from a data centre to a cloud infrastructure may not deliver the full capability of cloud services: applications should be broken down into API-connected microservices and use ‘cloud-native’ components to optimise costs, resilience and availability.

IT is not the only part of a company impacted by cloud - the transformation causes a broad rethinking of the company’s processes, operating model and resources. For example, a lack of cloud talent is another potential major roadblock. Given the broad range of impacts that moving to the cloud may cause for organisations, a transformation constitutes an upfront investment that makes many organisations hesitate.

Cloud success stories

“Originally a brick-and-mortar retailer, adidas quickly became an ecommerce champion. How? By prioritizing the digital experience and investing in a suite of Salesforce products that allow the company to get much closer to consumers.” [12]
Key success factors for cloud transformation

Using cloud is not just a project: it is a fundamental change in the DNA of a company. To benefit fully from the advantages of the cloud, organisations need a digital transformation that goes well beyond a simple project. Deloitte recommends an approach to cloud transformation that consists of six phases, from strategy to cultural change.

Cloud strategy

Define your objectives for the cloud. The benefits must be clearly articulated – greater operational efficiency, flexibility, agility, increased revenue generation, reduced costs, enhanced security, better risk management, return on investment, and so on. Cloud strategy should follow IT strategy, which should align with the business strategy. Cloud initiatives should always be linked to business value and fit with the overall corporate strategy. Deloitte has developed a framework of six building blocks on which to construct a sound cloud strategy.

Many large organisations already have a ‘cloud first’ strategy in place, meaning that with any project they look to the cloud before considering the in-house or traditional outsourcing alternatives. A cloud strategy should take into consideration not only the present but also the future; embracing cloud enables organisations to adopt tomorrow’s technology more easily, blockchain being just one example.

“Not having a roadmap would be really dangerous these days because the pace of transformation is speeding up in every industry. Be on the lookout for quick wins and use them to validate your direction.” [13]
Deloitte’s cloud strategy framework

Roadmap
- Adoption pace
- Enabling initiatives
- Interdependencies

Financial impact
- Governance
- Talent
- DevOps

Organisational impact
- Value case
- Savings
- CapEx and OpEx impact

Baseline
- Current state IT footprint
- In-flight/current projects
- Issues and opportunities

Vision
- Business alignment
- Guiding principles
- Pace

Strategic scenarios
- Public/Private/Hybrid
- Key platforms
- Transformation approach

Architecture & Engineering
- Integration architecture
- Tooling
- Technical architecture

Security, Risk & Compliance
- Regulatory impact
- Security controls
- Data privacy implications

Figure 6 - source: Deloitte
Risk management

Moving services to the cloud transfers some of the responsibilities for risk management to the third party cloud service provider. However, it is only the management of the risks that is transferred: accountability for the risks still resides with the organisation, and not the cloud service provider. The company’s operational risk management framework must therefore take into account the special circumstances arising from cloud services adoption. An important element of the framework should be to classify the information assets - such as intellectual property, customer databases and financial information - so that the inherent risks can be managed.

The service contract should include terms that define the right to audit the cloud environment, and organisations must also prepare an exit strategy with associated contractual conditions in place, a business continuity plan covering the full scope of the cloud service, IT service management procedures and controls, and a redesigned operating model to ensure the right team structure and capabilities are in place to manage the cloud services. It is particularly important to consider legal and regulatory compliance during their risk assessment, which should involve the risk management functions and other stakeholders, and should be based on the ‘three lines of defence’ model.

In order to mitigate third party risks stemming from a cloud service provider, organisations should follow a holistic approach, analysing risks into categories or ‘risk domains’ and mapping them to operating model components in order to ensure monitoring and controls are effective on an ongoing basis.

Within the organisation, a risk management framework should be created for the cloud, and a clear risk report should be drawn from it. It is essential to understand the operational and compliance risks of outsourcing. Plotting a route through all the risks and regulatory complexities will ensure that the company gets the planned benefits from the cloud.

Due diligence should be a standard requirement for any outsourcing initiative, in order to understand the key risks and embed controls into the contract. Supplier risk must be factored into the equation. The risk of intruders gaining access to IT systems has forced organisations to improve cyber security. Cyber risk deserves special attention and security must be tight. Complying with national laws and regulations on data is a thorny problem that must be addressed and the full implications of GDPR and other relevant data secrecy and data privacy laws must be understood and adhered to.

Compliance with national laws and regulations on data is a problem that must be addressed. Who owns the data? In which countries should the data be stored? Who is permitted to access the data stored in another country? Data hosted on cloud services is subject to the laws and regulations of the country where the data is stored. The European Union’s rules also apply to data held outside its territory. The General Data Protection Regulation (GDPR), which came into effect in May 2018, is designed to improve data protection for EU citizens whose data is collected, stored and processed by organisations, but the scope of the Regulation extends to companies using servers outside the EU, if those servers hold data on EU citizens. The full implications of GDPR and other data privacy laws must be understood.

### Operating Model Components

- **Governance and oversight**: The organisational structure, committees, and roles and responsibilities for managing third parties
- **Policies and standards**: Management expectations for the management of third parties and related risks
- **Management Processes**: Processes to manage risks across the third-party lifecycle
- **Risk culture**: Tone at the top, clarity on risk appetite, appropriate training and awareness. To promote positive risk culture
- **Tools and technology**: Tools and technology that support third-party risk management processes
- **Risk metrics and reporting**: Reports identifying risks and performance associated with third parties, tailored towards multiple levels of management

### Management Process Detail

1. **Plan, Evaluate and Select**
2. **Contract and On-board**
3. **Manage and Monitor**
4. **Terminate and Off-board**

Controls and risk assessment processes are embedded in each of the four phases of the lifecycle.

*Figure 7 - source: Deloitte*
Governance

Organisations must define how decisions specific to cloud solutions will be made. Governance processes relating to the use of cloud services should be developed: who is able to request them, how many resources can be provided, and what approval(s) are required. In addition to setting quotas, providing visibility and reporting usage will help to hold users accountable. Organisations should establish a robust cloud governance structure, with three pillars of governance and ranking of elements within each pillar from strategic to functional.

How can governance be made sufficiently flexible to manage risk while supporting innovation and cost reduction? Establishing governance and controls provides direction for the adoption of the cloud by an organisation. These should consider controls for business processes, applications, data, infrastructure, and organisational management. Structured governance is required to monitor performance continually, improve service effectiveness, and align investments with business objectives.

To avoid new or additional risk, governance should ensure proper due diligence and security, and should specify standards for which services are permissible and which are not. In practice that could mean for example that business services can get integrated and used, as long the service is built on Microsoft or Google cloud components, if these vendors have already been approved for use by the company.

“Organisations will need to embed conduct and culture throughout their processes and governance structure, and especially at key influencing points such as customer onboarding, new products, sales practices, training, and incentive compensation.” [13]
Deloitte’s IT governance framework

**Governance Domains**
- Planning & Alignment
- Principles & Guidelines
- Architecture & Standards
- IT/Business Alignment
- Infrastructure Strategies
- Prioritisation & Investment
- Org Planning & Sourcing
- Service Metrics
- Service Monitoring & Reporting

**Governance Bodies**
- IT Investment Advisory Council
- IS Leadership Team
- IT Portfolio Management
- Architecture Standard Working Group
- IT Budget Preparation

**Process Areas**
- Business Relationship Management
- Corporate Governance, Compliance and Security
- Customer Relationship Management
- IT Strategy & Business Alignment
- Investment Portfolio Management
- Architecture Management
- Service Portfolio Management
- Project Portfolio Control / Assurance
- Programme & Project Management
- Solution Development
- Service Transition
- Service Operation
- Workforce Management
- Technology & Infrastructure Mgmt.
- Quality & Assurance Management
- Financial Management
- Sourcing and Procurement Mgmt.
- Vendor Relationship

**Operational Groups**
- IT Service Delivery
- Information / Data Management
- Project Steering Committees

Domains drive what types of decisions need to be made.

Bodies define who makes the decisions and who is responsible for implementing, supporting and monitoring.

Processes define how the decisions are made and how they are implemented and supported.

Figure 8 - source: Deloitte
Financial analysis

A business case should be developed to justify the migration of workloads to a cloud environment, in order to mitigate risks relating to cost management. Organisations should analyse the quantitative financial benefits of transition to the cloud. C-Suite executives want to know: What are the cost drivers for cloud transformation? What are the high-level benefits of embarking on a cloud transformation? How may these benefits be realised? Financial benefits from cloud will not be limited to IT, since they will impact time-to-market, innovation and competitiveness (as outlined earlier in this report). While these business benefits must be considered in each case, they may be difficult to evaluate quantitatively and are heavily dependent on the organisation’s structure and strategy. We therefore propose three areas for analysis in building a financial case for the cloud from an IT perspective.

“Organisations are looking for clear directional impact by analyzing the quantitative benefits of cloud. C-Suite IT executives want to know: What are the net costs and benefits of embarking on a cloud transformation? How can we capture the cloud value to offset transformational costs?”
Cloud success stories

Cargill made drivers safer and delivery administration more efficient: Cargill developed a mobile application on top of SAP Cloud Platform and leveraging the iOS SDK to engage drivers and other stakeholders involved in the process. [15]
Cloud migration

Applications may follow different migration paths, ranging from a simple ‘lift-and-shift’ where applications are re-hosted in a cloud environment without further changes, to a complete refactoring of the application using ‘cloud native’ components. Each approach presents pros and cons: for instance a complete refactoring may prove costly and may generate vendor lock-in, but at the same time enable applications to fully leverage cloud capabilities such as elasticity, high availability and high resiliency. Re-platforming applications on PaaS is a trade-off chosen by many organisations, since in many cases it provides most benefits from the cloud without the lock-in.

Transporting legacy applications to the cloud is a thorny challenge for many organisations – for this reason Deloitte acquired Innowake® [16], which can translate Cobol/PL1 code into Java code, helping to refactor legacy software into cloud-ready applications. In case of mass migration, an Application Migration Centre of Excellence should be created to benefit from efficiencies and economies of scale. After migrating, ensure shutdown of legacy on-premise systems to avoid parallel operations and costs.

For mass migrations, organisations should set up an Application Migration Centre of Excellence to benefit from economies of scale and efficiencies

Figure 10 - source: Deloitte
Cultural Change

Cloud is not just about technological transformation, but also about adapting the corporate culture to use of the cloud, and adopting a new mind-set for working and collaborating in order to leverage the technology. People need to start thinking ‘cloud’, for example by adopting DevOps practices. ‘DevOps’ is a contraction of ‘Development and Operations’, and is a paradigm for software production which consists of streamlining the lifecycle from development to production. DevOps enables companies to increase their agility and innovative abilities whilst reducing risks and delivery cycles. Corporate culture needs to change, from a mind-set focused on static, policy driven operations towards small entrepreneurial units that have a much greater freedom of choice. Business leaders should embrace the entrepreneurial spirit and empower business units to take advantage of the flexibility offered by the cloud in line with the defined governance structure. What if analytics and benchmarking tools could be accessible in much finer (‘granular’) detail, enabling smaller business units to make better-informed decisions?

Organisations should follow a culture change roadmap to bring people along and make a cloud transformation not only a technical implementation but an end-to-end transformation across all dimensions of the company.

“Clear ambitions give people the opportunity to understand where they can push boundaries and drive innovation. New generations of professionals tend to seek experimentation, innovation, and progress. By including cloud in your corporate culture, your organisation can become more and more ready for the digital world.”
Deloitte’s Culture Activation Roadmap

**Strategy**

Define a compelling cultural aspiration aligned to the organisation’s strategy

“Framing the challenge”

What challenge are we trying to resolve? What outcome are we seeking to deliver through organisational culture?

- Determine scope, objectives, purpose and business challenges drawing upon culture principles and culture transformation best practice
- Clearly articulate strategic intent and culture aspirations

**Insight**

Use cultural diagnostic, interviews and data analysis to define gaps & desired attributes

“Understand, explore, synthesise”

What do stakeholders think/feel/say about the current culture? What insights can help us realign our culture?

- Explore stakeholders and the system within which they reside
- Synthesise insights and define design principles & hypotheses
- Identify ideas to address unmet needs and harness opportunities

**Activation**

Activate culture through design thinking, agile executions, our culture tools and accelerators

“Design for best value”

What solutions will deliver the culture we need? How should we manage culture implementation?

- Develop culture solution prototypes
- Test and refine (in loops) culture prototypes to determine best value
- Decide and implement culture solutions which deliver best value
Six aspects of culture that might need to change

- Stories
- Symbols
- Rituals & routines
- Influence & decision making
- Processes and systems
- Structures & informal networks

“There has to be a comprehensive people change management programme, one that makes it clear to employees that cloud is not just a cost-reduction exercise or technological change but a re-thinking of the business; and one that shows them how to take advantage of the flexibility and agility that cloud offers, and build new things on top of that. Cloud has to be embraced. If people embrace it, then the rewards will follow.” [3]
Cloud cyber security

Cloud is not only redefining the IT landscape but also how security measures are designed and implemented. In particular, the migration to a virtual data centre forces organisations to rethink security and privacy from the ground up. At one time, the security of cloud service providers was a significant concern for many companies, worried that cyber attackers would find it easier to penetrate the cloud than on-premise systems. Even today this issue – together with privacy concerns – is one of the biggest barriers to cloud adoption. However, cloud security (at least at the hyperscale cloud service providers) can in fact be a positive argument for adoption of the cloud, since cloud service providers invest more in security than most multinational companies will ever be able to. Security is in effect part of the main business process of cloud service providers, and not just a support process.

Security of the cloud

The cloud service provider is responsible for the reliability, security and compliance of the services that make up the cloud. These include responsibilities for the integrity of the hardware, software, networking and facilities that run the cloud services.

Security in the cloud

Organisations should implement controls for elements which they are responsible for. This will depend on the cloud services they use. For example, if an organisation transfers an application to an IaaS environment, it is responsible for some of the infrastructure security and all levels above (see Figure 13). On the other hand, organisations using SaaS solutions are only responsible for the data, governance and security compliance.

“Through 2022, at least 95% of cloud security failures will be the customer’s fault.” [17]

It is important to understand that the division of responsibilities for securing cloud workloads differs between the types of service. However, the liability for data stored and processed in the cloud, as well as overall security of a cloud-based solution, always remains with the organisation using the cloud services.

What is new from cyber security perspective in the cloud?

As businesses move to cloud computing, employees in principle are able to access their work applications and corporate resources through almost any internet-connected device. As a result, they want and expect 'anywhere-access' on a device of their choosing. Since data is transmitted through unsecure public internet networks, the 'old' security solutions for in-house systems do not offer the protection required. In fact, perimeter-based security has not been effective for some time against modern cyber threats; and with cloud computing it is even less effective. There is also a shift from segregated IT systems to a cloud environment where virtual machines and networks share the same physical resources, posing different security challenges for cyber professionals.
Cyber security perspective in the cloud

There are a variety of cyber risks associated with moving to the cloud. While the general threat stays the same, cloud introduces new attack surfaces that need to be constantly monitored.

- **Third-party Risk**: Organisations are dependent on cloud providers’ controls.
- **Concentrated Risk**: Cloud providers are a bigger target because “that’s where the data is” with or without cyber controls.
- **User/Shadow IT**: Business and consumers using cloud with or without cyber controls.
- **Modern Attack Surface**: The walled organisation (i.e. with clearly defined IT frontiers) is replaced by a hybrid, more complicated technology environment.
- **Controls Gap**: Traditional cyber risk controls need to extend to the cloud at a time when many organisations are barely keeping up with existing threats.

*Figure 14 - source: Deloitte*
User/Shadow IT
The accessibility and ease of subscription to cloud services created a situation in which employees were able to use cloud applications for work-related data exchange that were not approved by the company IT. Similarly, business units could buy cloud services they wanted without following procurement procedures, or giving consideration to security or privacy issues. There were various reasons for this, but the consequences were often the same – breached accounts, leaked data, malware spread across the company. Organisations need to have an answer to this problem in order to protect its digital assets. A key element is to be able to identify and manage the cloud services that are used or could be used from the organisation’s managed devices and networks.

Concentrated Risk
An accumulation of valuable items will attract the attention of people with malicious intent. This is true for valuable physical items as well as information. The risk of a successful attack is greater for a cloud service provider because it would probably involve the information of many different customers. Companies have to rely on their cloud service provider to address and mitigate many of the risks since they cannot manage the risks themselves within the shared responsibilities model. Cloud service providers in their turn are highly motivated to invest significantly in defence measures to maintain their ability to withstand the threats and make attacks on them cost-prohibitive. In order to select the right cloud service provider, organisations should examine closely how cloud service providers are managing such risks and what kind of contractual liability they have for a breach of data security. In addition, they should examine additional risk mitigating functions.

Third-party Risk
When a company uses cloud services it connects its infrastructure to a cloud service provider’s. Security for the overall system depends not only on the organisation using the cloud services, but also on the cloud service provider’s security controls. The cyber risks are the same as with the on-premise infrastructure. This means that physical security of the cloud service provider equipment, software and hardware updates, internal governance processes and technical controls have to be assessed by a potential user in accordance with its own security and privacy requirements. Organisations considering a cloud solution should insist on seeing the cloud service provider’s controls and certifications, and check whether there is a single place where such documents are stored (e.g., a trust portal or similar). If gaps in controls are identified, the organisation should either switch to a different cloud service provider or close the gaps with its own security controls.

Modern Attack Surface
New technology and digital solutions bring new methods of cyber attack and make old ones obsolete. The cloud is no exception. Employees of cloud-enabled organisations often work from any devices anywhere on the planet, making it more difficult than ever to protect the organisation’s data. Not only must the intranet and cloud workloads be secured, but every user device should also have technical measures in place to protect data. To add to the problem, all the cloud-enabled devices in the organisation must be monitored 24/7 and in real time, since once a security breach occurs, it won’t take long for the hacker to target the ‘crown jewels’ of the organisation’s information and data.
Controls Gap
Using cloud services requires a re-think of the controls an organisation should use. Monitoring and securing a cloud-only or (more often) hybrid environment needs new methods, processes and technology, because even the most mature and safe cloud service provider technology still depends on customers using it in a secure way. Risks of failure are high - attacks can go undetected, data can be lost, and reputation can be damaged.

Addressing cyber risks in the cloud
Cyber risks need to be addressed as organisations embrace cloud, mobile, social and analytics technologies. Organisations should develop a cyber risk framework that focuses on delivering end-to-end cloud cyber risk capabilities, incorporating considerations about privacy, security, monitoring, incident response, and governance for integrating cloud services across the organisation. In Deloitte’s Cyber Risk Management framework there are three pillars (“Secure. Vigilant. Resilient”) and seven cyber risk domains.
Secure
The Secure pillar of a Cyber Risk Management framework provides protective elements. It contains three domains. The first domain, **Network & Infrastructure security**, covers the virtual infrastructure with a focus on protecting network traffic, hardening endpoints like API gateways and protecting services. **Identity & access management**, the second domain, is designed to help address different cloud requirements for authentication, authorisation, access governance and accountability. Specific elements include multi-factor authentication, privileged access management and access certification. The third domain, **Data Protection**, covers controls recommended for protecting data at rest, in transit, and in use: core elements are encryption, key, and certificate management.

Vigilant
The Vigilant pillar involves the provision and integration of information, from both on-premise and cloud sources, to enable security teams to identify, detect, and respond more effectively to security threats. The domain **Logging & Monitoring** involves techniques for detecting security events, collating a multitude of log sources, and integrating with a Security Information and Event Monitoring (SIEM) system to monitor the cloud, to enable the organisation to identify where critical data assets reside, who accesses them, and how they are used.

Resilient
The Resilience domain covers designs for ‘always on’ capabilities, and new models for contingency planning, recovery, and resilience. As cloud computing becomes a more integral part of core business operations, it becomes necessary to reduce downtime due to disruptions, from minutes to seconds. A mature cloud service provider provides accessible features such as scalable, on-demand APIs that allow companies in a cost-effective way to create redundant infrastructure and back-ups with low latency to reduce disruption. Other design concepts and tools are cross-region replication of virtual instances, multi-availability zone deployments, and data archiving services.

The domain **DevSecOps**, encompasses secure configuration, vigilant security monitoring, and resilient deployment designs. It is worth mentioning that while IaaS provides the building blocks for resilient systems, their effective implementation still relies on the development teams and no availability is guaranteed by the cloud service provider at the application level, since their SLAs stop at the infrastructure level in the case of IaaS. On the other hand, SaaS solutions and managed cloud services can provide SLAs at the software level, giving contractual guarantees of higher level services resilience compared to IaaS or PaaS providers.

The aforementioned security concepts are brought together to achieve business goals with secure software. To define and manage the cyber risk requirements specific to the organisation, the **Governance, Risk, and Compliance (GRC)** domain provides guidance for establishing governance, policy, standards, processes, technology, and reporting, in order to achieve the goals of the organisation.

In conclusion, through the use of a cloud security framework an organisation is able to design, implement and operate cloud services securely and benefit from the inherent security features that cloud service providers provide as part of their service.

“It is no longer acceptable for security teams to hold back cloud initiatives with unsubstantiated cloud security worries. Security and risk management leaders should be tasked to develop new approaches to securely and reliably leverage the benefits of SaaS, PaaS and IaaS.” [18]
Selecting the right cloud service provider

Figure 16 - source: Deloitte
Data security, data governance and business policies

What is the cloud service provider’s position regarding the US’ CLOUD Act and the provision of client data to foreign governments? Where are its data centres located? Since security and compliance regulations vary from country to country, organisations operating worldwide need to be aware of the jurisdiction in which their cloud service provider hosts data, how the data is protected from unauthorised access, and what are its policies regarding local and foreign laws on matters such as data disclosure to foreign authorities (e.g. CLOUD Act).

Evaluate the cloud service provider’s capabilities in terms of security operations, security governance and system security, and make sure that it has demonstrable risk-based controls aligned with your organisation’s own security processes and policies. Verify that user access and actions are auditable and are in alignment with the security responsibilities as set out in the organisation’s business policies or service contract.
Compliance with regulations, certifications and standard

Ensure that the cloud service provider follows compliance guidelines that apply to your industry and organisation. Whether you are committed to GDPR, SOC 2, PCI DSS, HIPAA, ISO 27000 series or some other standard, make sure you understand what it will take to accomplish compliance once your applications and information are in a cloud environment.

Ensure you understand where your duties lie regarding compliance, and which aspects of regulations the cloud service provider will enable you to comply with. Verify that the provider’s compliance certificates are valid and obtain guarantees of resource allocations such as headcount and budget to maintain these standards in the future.

Service dependencies and partnerships

Cloud service providers may have relationships with other providers to deliver their services. Evaluate these relationships and the levels of accreditation, technical capabilities and staff certification of the underlying providers. Analyse dependencies involved in the provision of the cloud service and look for potential flaws or mismatches with the cloud service providers claimed certifications. SaaS providers typically build their services on top of major IaaS providers, so it must be clear from where and how the service is being delivered, and if this fits with the organisation’s own policies.

Integration with other systems, hybrid cloud capabilities

Consider how processes or data hosted in the cloud will integrate into your workflows now and in the future. For example, if your company has already invested heavily in a provider’s ecosystem (e.g. Microsoft’s Office 365), it may be a good idea to use cloud services from this same provider (in this case Microsoft Azure), since some of them grant licences and often free credits to their customers.

Integration between a private and public cloud enables organisations to create efficient, coherent hybrid applications. This integration can be facilitated by using the same stack in the public cloud as in the private data centre. OpenStack provides an open-source and open standards stack to build highly compatible applications with highly reduced lock-in and enables more customisation than branded stacks. Managed versions of OpenStack can be delivered by vendors such as Rackspace, RedHat, IBM or Suse. SaaS solutions should provide APIs to connect applications to other data sources and interact with the organisation’s systems.

Reliability and performance

Analyse performance of the service provider against their SLAs for the last 6-12 months and the cloud service providers transparency with audit reports and control frameworks. Downtime is inevitable and every cloud service provider will experience it at some point. What matters is how the cloud service provider deals with any downtime. Ensure the monitoring and reporting tools on offer are sufficient and can integrate into the organisation’s overall management and reporting systems. Ensure that the selected cloud service provider has established, documented and proven processes for dealing with planned and unplanned downtime.

Evaluate the cloud service provider’s remedies and liability limitations when service issues arise, as well as its disaster recovery provisions, processes and its ability to support the organisation’s data preservation expectations, including recovery time objectives (RTO). This should include at least criticality of data, data sources, scheduling, backup, restore and integrity checks.
Contracts, commercials and SLAs
Cloud agreements can appear complex, SLA definitions in particular. Cloud service providers often use complex terms and conditions that make it difficult to compare the service levels of different providers. It is important to understand the level of service promised by each cloud service provider and perform a market research to compare offerings and get the best value for money.

Business alignment
Ensure that the chosen cloud service provider understands the business of the organisation and the precise objectives it seeks to achieve with the cloud. The focus should be on high-level business value such as streamlining product delivery or reducing time to value, rather than low-level, technical indicators such as server up-time or database throughput.

Organisations within a vertical industry such as banks should make sure that the cloud service provider understands the industry; in certain cases, this can mean choosing a smaller specialised player like Rackspace in preference to a hyperscale provider, in order to leverage industry-specific tools.

Managed Service Providers (MSPs) deliver managed cloud services and act like a broker between the end-user and an IaaS or PaaS provider. MSPs provide an additional layer of management to handle contracting, financial management, security and compliance, and can also deliver industry-specific capabilities.

Business health, continuity and company profile
While the assessment of the technical and operational capabilities of a potential supplier is obviously important, you must also take time to consider the financial health and profile of your shortlisted providers.

If a cloud service provider gets into trouble, it may not have enough financial resources to meet its obligations or refund losses; to this end, a business continuity plan in case of a default of the cloud service provider including notification period, data migration support and intellectual property must be carefully prepared.

Vendor lock-in and exit planning
Vendor lock-in usually stems from proprietary technologies that do not integrate with those of competitors, or from inefficient processes or contract constraints. The portability of applications may be impacted if they heavily rely on unique proprietary components. Ideally an organisation should choose value added services that have competitive similar alternatives, monitor the availability of those services in the market to spot risks of lock-in early enough, and plan an exit strategy at the start of its relationship with a chosen cloud service provider.

Technologies and service roadmap
Understand where the cloud service provider is heading over the next four years and make sure it aligns with the organisation’s cloud and business objectives. Does the provider plan changes that would involve re-coding applications? Will there be a change in its certifications or security standards? Assess the impacts on workloads and take them into consideration when building the case for cloud.
Another short quiz

Is your organisation getting cloud right?

- Yes, we’re already in the cloud
- Not sure, and the next steps seem quite cloudy
- We haven’t started our cloud journey yet – some advice would help
Conclusion

Cloud provides transformative opportunities for organisations and is a vital competitive component in today's challenging market place. Cloud is not an easy technology to adopt, but the potential benefits and opportunities outweigh the challenges and risks associated with cloud transformation.

To maximise cloud’s added value, an organisation should follow a structured approach, starting with the definition of a clear strategy involving a wide range of stakeholders. A shared vision and expectations should emerge from the cloud strategy, including knowledge of options, understanding of business drivers covering both opportunities and risks, proper planning, disciplined execution and ongoing governance and management.

This report has set out the steps an organisation should consider in order to get things right and become a best-in-class cloud-first company that thrives in today’s competitive market.
